

Future Enhancement – MCP Integration (Version 2.0)

The current implementation follows a **service-oriented architecture**, where all external integrations (LLM, embeddings, vector database, storage, and job discovery APIs) are encapsulated within a dedicated Service Layer. This approach keeps the business logic independent from the underlying implementation while simplifying development, testing, and maintenance.

Although **Model Context Protocol (MCP)** is not included in Version 1.0, the architecture has been intentionally designed to be **MCP-ready**. Because the agents communicate only with the Service Layer, these services can later be exposed as MCP servers with minimal changes to the overall system architecture and without affecting the agent workflows.

The primary objective of Version 1.0 is to demonstrate the core concepts of Agentic AI, including:

- Multi-Agent Collaboration
- LangGraph-based Workflow Orchestration
- Human-in-the-Loop Decision Making
- Retrieval-Augmented Generation (RAG)
- Tool Integration through a Service Layer
- Support for both Cloud-based and Local LLMs

Version 2.0 will focus on extending the platform through MCP integration, enabling standardized communication with external enterprise systems and third-party tools. Future enhancements may include integrations with Applicant Tracking Systems (ATS), recruitment platforms, calendars, email services, document management systems, and HR software.

Additionally, while Version 1.0 is designed primarily for job applicants, Version 2.0 will introduce dedicated workflows for recruiters and hiring managers. This will transform the platform into a collaborative AI recruitment assistant capable of supporting candidate sourcing, CV screening, interview scheduling, candidate evaluation, and recruitment workflow management.
